A. INTRODUCTION

Good population forecasts are generally an essential component of most other types of forecasts, be these in the Private Sector in areas such as investment, marketing, business and economic forecasting, or in the Public Sector in the planning of government programs, services and facilities. Population projections that have been produced by various groups and individuals in the past have usually concerned themselves with either the Province as a whole or with a particular region of it. In November 1974, B.C. Research published the first comprehensive set of regional projections for the Province of British Columbia, with projections for every Regional District and School District. In September 1979 these projections were updated, incorporating the 1976 Census data as well as more recent birth, death and migration statistics. This report presents projections of school age populations based on this latest B.C. Research publication*.

These school age population projections cover the years from 1979 to 2001 and are given for single years up to 1986 and for every fifth year thereafter. The age distribution of the population is broken down by single-year age groups for each of the forecast years.

Separate projections are given for each of British Columbia's 75 School Districts (Chapter D). The projection for British Columbia as a whole (Chapter C) is the sum of the individual school district forecasts. At the end of the manual, in Chapter F, a map is presented showing the geographical location of all the School Districts in B.C. A description of the assumptions made in the projections and some technical explanations are given in Chapter B.

In developing these projections, an attempt was made to compare, where possible, the general trend of these forecasts with those prepared by

* B.C. Research. British Columbia Population Projections, 1979-2001 by Glen C. Forrester and Stan Chow. Vancouver: B.C. Research, September 1979.

other groups. Notable in this regard were projections prepared by individual Regional Districts, Statistics Canada, the B.C. Ministry of Economic Development and, for school ages only, the school enrolment projections prepared by B.C. Research for the B.C. Ministry of Education, Science & Technology.

The projections presented in this report were prepared by the Management Services Division of B.C. Research. This Division carries out a great deal of work in the areas of forecasting, economic studies, educational planning, operations research and computer modelling. This report was prepared on behalf of the Educational Data Services branch of the B.C. Ministry of Education, Science & Technology. The figures presented here were derived from the total B.C. population projections referred to earlier. This larger population study was undertaken by B.C. Research in recognition of the need for such statistical information. The purpose of that work was to provide a good and comprehensive set of projections which could serve as the commonly accepted basis for most forecasting and planning studies in British Columbia. It is expected that this school age population manual will prove to be an invaluable aid and reference source to individuals and groups who are concerned with educational planning.

Users who are interested in the most up-to-date estimates of current populations in British Columbia are advised to contact the Population and Social Statistics Division of the B.C. Ministry of Economic Development, Victoria, B.C.

Limitations

The projections in this report were calculated on the basis of past trends and under specific assumptions as to how these trends would continue. An attempt was made to select reasonable assumptions about the future course of the components of population change and thus implicitly to "forecast" future population. However, the figures presented in this report are labelled conservatively as projections

rather than forecasts in order to emphasize the difficulty of projecting population accurately (see Tables I and II concerning the success of previous population projections) and to emphasize the importance of considering the purpose for which the figures are to be used. In many situations population trends are sufficient information on which to base decisions. In others, accurate predictions are essential.

These projections are, at best, indicative of past trends and should not be taken as specific predictions. In areas where future development patterns are substantially different from past historical patterns, these projected populations may not be realized. Changes in factors such as government policy, land use, zoning and economic development will affect future population growth rates. In these cases the projections published here should be, nevertheless, of value as a basis for making better predictions in light of new facts.

B. ASSUMPTIONS AND TECHNICAL EXPLANATIONS

The procedures and assumptions described in this chapter are similar, but not identical, to those used in preparing the November 1974 B.C. Research publication "British Columbia Population Projections, 1974-1996". Comparisons of the projected 1976 populations in that publication with the 1976 Census data prompted a number of changes to the earlier methodology. Table I provides a comparison of the actual 1976 B.C. population with a variety of published projections. As can be seen from this chart, the B.C. Research projections were extremely close to the actual total province figures. Table II shows the regional figures and at this level the B.C. Research projections did not fare as well as anticipated. Consequently several modifications were made to the procedures and a more deliberate attempt was made to set net migration levels in response to information from regional districts. It is expected that the alterations to the methodology will improve the regional forecasts.

The projections were calculated at the School District level, with Regional and Provincial figures being obtained by summation. The basis of the projections were school district birth, death and census data for 1966, 1971 and 1976. Birth and death statistics were obtained from the B.C. Division of Vital Statistics while the Census data were aggregated according to school districts by the B.C. Ministry of Economic Development. As these data were obtained at five-year intervals the actual population projections were produced on a five-year grid of age and time up to the year 2001. Populations for single years up to 1986 and for single-year age groups have been obtained by polynomial interpolation on the five-year grid.

The basic procedure behind the population projections was that of "cohort survival", whereby age groups at a particular point in time are systematically promoted into the next higher age group at the next point in time. This is done using "cohort change rates". For example, the 20-24 year age group in 1976 becomes the 25-29 year age group in 1981, upon multiplication by the appropriate cohort change rate.

B.C. TOTAL	44,119	+0.2						

*Actual difference or percentage difference in the total population projected in the B.C. Research publication "British Columbia Population Projections, 1974 - 1996" as compared with the actual 1976 Census results. A positive difference indicates an over-estimate while a negative value indicates an under-estimate of the actual population.

A total of six factors are involved:

- cohort change rates;
- age-specific birth rate;
- children/births ratio;
- age-specific death rate;
- residual net migration;
- migration factors.

These six factors are discussed in detail below.

An important assumption in calculating the first four of these factors is that specific local trends would be dominant in the short-term, but that their effects would be reduced in time so as to approach the overall provincial trends in later years. This was achieved by exponential convergence from a specified initial value toward a specified final value. Mathematically, the form of the equation used was:

$$Y_t = Y_f + (Y_0 - Y_f) e^{-\beta(t-1)}$$

where: Y_t = the projected factor at year t

Y_0 = the factor's initial value

Y_f = the final value

β = the decay constant

t = the year as measured on the 5-year grid,
($t=1$ refers to 1981, $t=2$ refers to 1986, etc)

Thus, for 1981 the factor being projected would have an initial value equal to Y_0 and by the year 2001 it would be approaching a value equal to Y_f . The value of the decay constant β was usually set equal to 1.0 (equal to 5 years), with the result that the factor has a value equal to .98 Y_f by 2001. In this way anomalous short-term trends, which would be unreasonable to project far into the future, were attenuated in a systematic way. All School Districts were treated alike. However, since the projections were produced at the School District level, local deviations from the Provincial average growth rate are reflected in these projections.

1. Cohort Change Rates - These are defined as the population of an age group in a given year divided into the population of the next older age group five years later. The cohort change rates were projected using exponential convergence. The initial value for the projection was a weighted mean of the historical rates. One-third of the weight was given to the 1966-1971 value and two-thirds to the 1971-1976 value. Where the resulting figure fell more than two standard deviations from the current provincial weighted mean for that age group, it was brought up or down to that value. In this manner, short-term local anomalies were not allowed to continue into the forecasting period, whereas local trends were reflected in the projected figures. The final value was the historical, provincial weighted mean for that age group, weighted slightly toward 1.0. A weight of .22 was given the 1966-1971 value, .45 to the 1971-1976 value and .33 to a cohort change rate of 1.0. This weighting implies a slight equalization in the age distribution of the population in the long term, (i.e. the age distribution will become more evenly distributed according to age). Where convergence to this provincial mean caused a local historical trend of decline or growth to be reversed (e.g. initial value .9, final value 1.2) the final value was taken to be 1.0.
2. Children/Births Ratios - These ratios are defined as the mid-year population of the 0-4 age group in a given calendar year divided by the number of births in that same year. The children/births ratios were also projected using exponential convergence. The initial value was an arithmetic mean of the three historical ratios, weighted toward the most recent one to emphasize the current trend. One-quarter of the weight was given to the 1966 value, one-quarter to the 1971 value and one-half to the 1976 children/births ratio. The final value was taken as the historical, provincial arithmetic mean, using the same weighting scheme.

3. Death Rates - These rates are defined as the number of deaths occurring in a given calendar year divided by the mid-year population in the 50 and over age group*. These age-specific death rates were projected using the exponential convergence technique. The initial value was an arithmetic mean of the three historical rates, weighted toward the most recent one to emphasize the current trend. One-quarter of the weight was given to the 1966 value, one-quarter to the 1971 value and one-half to the 1976 age-specific death rate. The final value was taken to be the historical, provincial arithmetic mean using the same weighting scheme.

4. Birth Rates - The age-specific birth rates used in the projection technique are defined as the number of births in a given calendar year divided by the mid-year population of the 20-34 year age group in that same year**. When multiplied by 15 for the number of years between age 20 and age 34 and then by 2 for the fact that roughly half the population is female, the resulting value approximates what is normally referred to as the total fertility rate. The total fertility rate expresses the average number of children a woman will have during her child-bearing years. Over the past twenty years, there has been an astonishing drop in this rate (see Figure 2, page 17). By 1976 this total fertility rate had already reached a value of 1.72 which is well below the zero population growth level of 2.10. It did not seem reasonable to continue this downward trend much further into the future. Consequently two separate calculations were combined to produce the projection of age-specific birth rates.

Exponential convergence was first used to project the downward trend, starting with the initial value set at the 1976 age-specific birth rate. The end point used was that value which would be reached by a ten year linear extension of the historical downward

* The ages 50 and over were used as the basis for the definition of death rates and for subsequent projections of deaths since roughly 85% of the annual deaths occur within these ages.

** The ages 20-34 were used as the basis for the definition of birth rates and for subsequent projections of births since approximately 84% of total births are accounted for by births to mothers within these ages.

trend. A time constant of 10 years was used. Added to this exponential curve was a small linear increase in the birth rate. The start of this increase was taken as 1976 and its rise by 2001 was set equal to the mean of the historical 5-year percentage declines in 1966-1971 and 1971-1976.

The projection therefore assumes a slowing of the current sharply declining birth rates and a reversal of this trend beginning in 1988. A slow, gradual increase follows and by the year 2001 it assumes the birth rate will be back to the level projected for 1981. This method was applied on a school district basis. It acknowledges the significant drop in birth rates in the recent past, sets a reasonable limit to this decline, and projects a limited recovery from this drop.

In addition, the method took into account any contrary local trends and did not reverse these trends. If no decrease in the age-specific birth rate was observed, the 1976 rate was used throughout the forecast period. Thus, in this case, the projection assumes that the birth rate will hold constant.

5. Residual Net Migration - Estimates of the residual net migration were calculated from the growth being projected by the other factors. This was done by first computing the change in total population over successive 5-year periods. Then, dividing by 5 to get the average annual change and taking into account the projected births and deaths, this produced an estimate of the residual net migration. It should be noted that the residual net migration figures are not the same as actual net migration. The definition used is based on the change in total population over successive 5-year periods. Thus the calculation contains the effect of error in population measurement. Since population is normally orders of magnitude greater than migration, a small error in the

stock estimate can lead to a large error in the residual. Given the fairly loose translation of Census data from Enumeration Areas to School Districts, it is not surprising that the historical estimates of "residual net migration" differ somewhat from the actual migration recorded by Statistics Canada.

6. Migration Factors - The overall projections were constrained by the use of provincial, and in some cases local, migration factors. These were applied to the projected populations in order to keep the residual net migration estimates within what were considered to be reasonable limits.

These migration factors are essentially age-specific scaling factors by which the projection of cohort change rates can be adjusted. They were applied to each age-group on a weighted basis, with weights proportional to the distribution by age of provincial migration. Thus, since a higher proportion of migration occurs between the ages of 20 and 34 than for other ages, these age groups were more affected by the migration factors.

The total provincial residual net migration was held to the mid 20,000's until the year 1981 and then increased to the low 30,000's from 1981 to 2001. Within these provincial levels, some regional adjustments were also made. These are detailed below. In all cases these adjustments were small, generally a 5% increase or decrease on a historical trend.

Central Fraser Valley Regional District, (School districts 34 and 35). It was assumed that the historical trend of a large migration flow into Langley would gradually taper off over the next two decades due to the limited land area available for future development. Some of this migration, it was assumed, would be redirected towards Abbotsford. Thus the historical trend of migration for Abbotsford was adjusted upward slightly while the Langley trend was adjusted down.

Central Okanagan Regional District, (School district 23). Although migration has been growing very rapidly in this area during the past decade it was assumed that this would slow down slightly. Thus the historical trend was adjusted downward.

Columbia-Shuswap Regional District, (School districts 18, 19 and 89). It was assumed that the Revelstoke Dam project would increase net migration to the Revelstoke area during the next five years. Thus local migration was adjusted upward slightly over past trends.

Dewdney Alouette Regional District, (School districts 42 and 75). It was assumed that the Maple Ridge area in particular, would be able to continue attracting its most recent share of Lower Mainland growth. Thus migration was set slightly above the historical trend.

East Kootenay Regional District, (School districts 1, 2, 3 and 4). Growth in the Fernie area over the past 10 years has been extremely rapid due to the start up of major coal mining operations. While additional developments are in the planning stages, it was felt that it would be difficult for this area to sustain its historical growth rates. Consequently migration was adjusted downward slightly for the Fernie area, although it was still assumed to be at a substantial level.

Greater Vancouver Regional District, (School districts 36-41, and 43-45). Because of limits on the amount of available land in the municipality of Delta and due to transportation problems between Delta and the rest of the GVRD, it has been assumed that the historical growth trends for Delta would slow down considerably. Instead, it was assumed that this growth would shift towards New Westminster and, to a lesser extent, toward Burnaby and Vancouver.

Kootenay Boundary Regional District, (School districts 11, 12 and 13). It has been assumed that the recent work on the Seven Mile hydro-electric project (since 1976) would generate a moderate increase in the growth rate for the Trail area, at least in the short-term future.

Summary

As a result of the technical procedures applied, the overall set of assumptions can be summarized as follows:

1. It was assumed that birth rates will continue to drop but that this fall would gradually slow down. About 1988 the birth rate would start to increase very slightly. The result of these assumptions was to project a slightly increasing number of births in the province.
2. The death rate was assumed to hold reasonably stable. However, as a result of the age distribution of the population, the number of deaths was projected to increase substantially.
3. Net migration, the sum of both inter-provincial and international migration, was assumed to continue its drop from the early seventies and, after a brief period in the mid 20,000 range, to stabilize in the range of 30-35,000 per year during the mid-80's.

C. PROVINCIAL SCHOOL AGE PROJECTIONS

The school age population projections for the whole of the Province of British Columbia are given in Table III. This table is broken into two time periods going across the page. Under the heading of "Historical Years", the Canada census data are presented for three years: 1966, 1971 and 1976. These data are as at June 1 of the corresponding year. Under the heading "Future Years", the projected populations are given from 1979 up to 2001. They are given for consecutive years up to 1986 and for every fifth year thereafter. Vertically on the page, the population for each year shown is broken into single-year age groups, sub-totalled at five-year age groups, and totalled at the bottom. For the three historical years, only the subtotals are Canada Census data. The individual single-year age group figures were obtained by polynomial interpolation on the 5-year subtotals. The calendar year based births are also shown. The layout of this table is identical to that used for the School District projections in Chapter D.

Figure 1 illustrates the growth that has occurred in the Provincial population over the historical years (solid lines), and that is projected for the future years (dotted lines). On this graph, the population is broken into four age groups; 0-4, 5-14, 15-19 and 20-24. These age groups can be considered as a reasonable approximation of school related ages; Pre-School, Elementary, Secondary and Post-Secondary. The population in each group is represented by the distance between the successive curves. Figure 2 illustrates the growth in births. Explanations of the various terms used in this chart were given in the previous chapter.

Figures 3 through 6 present the projected population growth of the various School Districts for the 5-14, 15-19, 20-24 and 5-24 age groups respectively. The districts are ranked so that the fastest growing district, in terms of population, is at the top of the chart. The

*An approximation to the total fertility rate,
See definition in accompanying text

length of the horizontal bar beside each district's name represents the projected average annual growth rate during the 1979-2001 period. Thus, an annual growth rate of 4.0% indicates that the district is projected to grow at the average rate of 4.0% per year compounded over the 22 year time period. This is an average growth rate, the projected growth may actually be slower or faster than this average during certain portions of the 22-year period. The growth rate for the whole of the province is shown by the horizontal line labelled "B.C. Total". This provides a quick comparison of each district with the Provincial total.
